

**Taxonomy** of the LBD Product ontology

**Example:** Product ontology extended

**Taxonomy** of the LBD Product ontology

Comments:

A. Distinction between **bot:Element** and **product:Product** ?

- Bot:Element [rdfs:label “Building element”(en)]: “Constituent of a construction entity with a characteristic technical function, form or position”. E.g., walls, doors, windows, beams (?)
- “A product is hereby understood as any physical building element in a building that is made available by a specific building product reseller” (GoogleDoc)

B. **gr:ProductOrService** is more general than **bot:Element**:

- gr:ProductOrService is NOT restricted to the building domain

**Taxonomy** of the LBD Product ontology

### Comments:

C. What is **product:Product** meant to model?

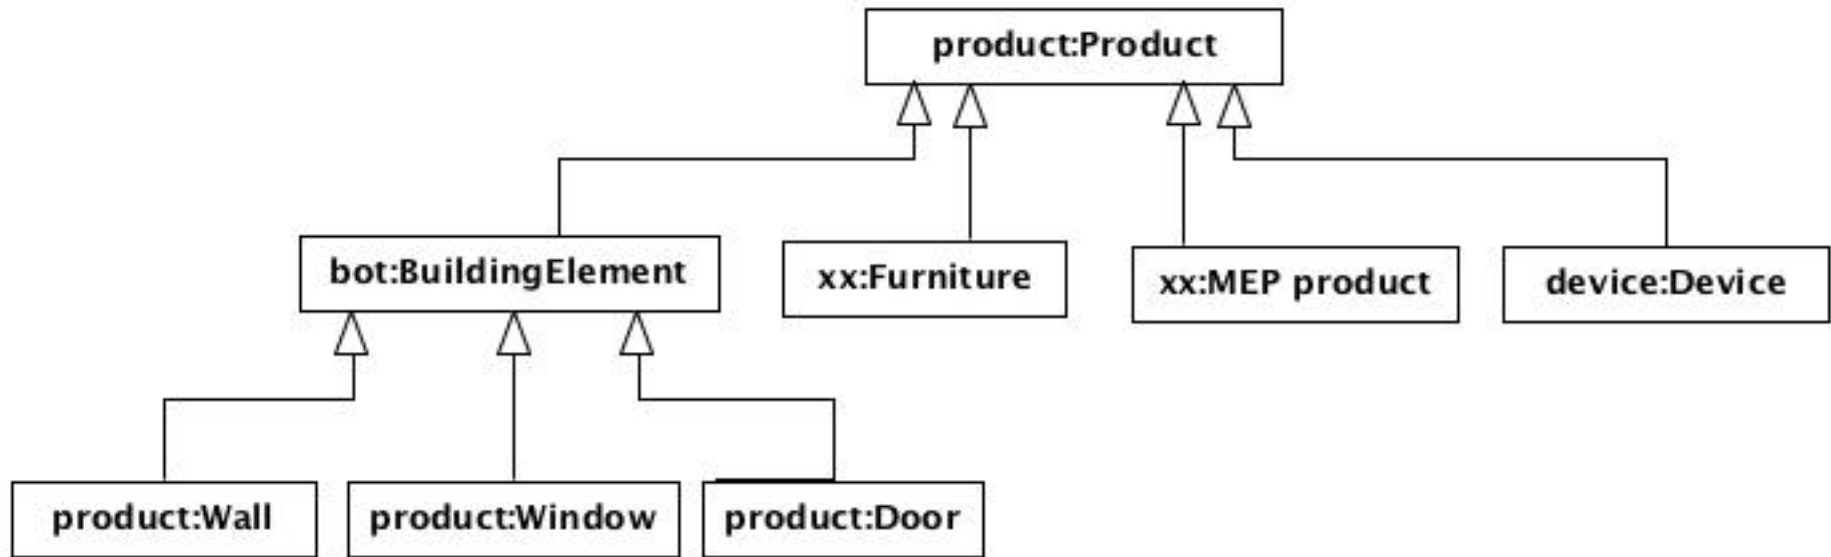

According to Mads (see notes\_MHRA.doc):

“product:Product was supposed to be the upper class that holds sub-products such as **building elements, MEP equipment, furniture** etc.”

If we keep this approach:

- **product:Product** should NOT have to be restricted to “physical building element in a building” – **cannot be** a subclass of bot:Element

## Proposal

**product:Product:** a physical object or material that is manufactured or refined for sale.

- Upper-level class for product classes that are specific to certain domains
